RADIOCARBON DATING

M.J. Beech, D. Hull and S. Rowland

Three charcoal samples were collected from hearths during the excavation of structures DH 1.1 and DH 22.2, and were subjected to radiocarbon dating after the 2001 season. The samples were dated by the Scottish Universities Research and Reactor Centre (SURRC) at the University of Glasgow, in conjunction with the University of Arizona AMS facility. The results of this analysis are presented in Table 8. Radiocarbon calibration was made using the OxCal v.3.5 programme. Calibrated radiocarbon dates are calculated using the atmospheric calibration curve and 2-sigma values (95.4% probability). Figures in brackets in between the calibrated radiocarbon dates indicate the relative area under the probability distribution. The radiocarbon dating suggests a likely range of dates from the mid-17th to 19th century AD. There is only a 13.9 – 16.2% probability that the dates may fall in the early part of the 20th century.
